

Using Excls on the web site

It is very hard to add an excel form into a page if you want to contain the boxes around the items. You can do a copy from excel to the page in WordPress. But you will loose the blocks around the cells.

If this is ok for you then this is the simplest way to do it.

If you want to have the blocks around the cell this is the way I did it.

Using Libre Office software open the excel and do a file save as HTML . This will create a html file using the excel as the format. To make it look better I add a column before the data in the excel and place a "period" into the new column so it will display the column. If you don't the extra column will not be created as the column has no data and the html will ignore.

Now open the page you want to add this in. Erase the Table that is there and select on the right side the "TEXT" option rather than the visual. Copy and paste the excel html into the text page. Then save it . It will contains an exact copy of the original excel. This will preserve the exact look of the excel with colors. If you do not need the colors then Copy the excel to the standard visual page using the BLOCK option rather than the classic editor. It will save the excel with blocks but no color.
